## MinCostMaxFlow.cc 2/35

```
// Implementation of min cost max flow algorithm using adjacency
// matrix (Edmonds and Karp 1972). This implementation keeps track of
// forward reverse edges separately (so you can set cap[i][i]] !=
// copil[i]). For a regular max flow, set all edge costs to 0.
                                                                                            // funning time, O(|V|^{\prime}2) cost per augmentation max flow: O(|V|^{\prime}3) augmentations // min cost max flow: O(|V|^{\prime}4^{*}*{\it MAX\_EDGE\_COST}) augmentations

    (maximum flow value, minimum cost value)
    To obtain the actual flow, look at positive values only.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                \label{eq:mincostMaxFlow(int N):} N(N), cap(N, VL(N)), flow(N, VL(N)), flow(N, VL(N)), flow(N), dist(N), dist(N), width(N), dad(N) <math display="inline">\{\}

## JavaGeometry.java 10/35

```
// In this example, we read an input file containing three lines, each
// containing an even number of doubles, separated by commans. The first two
// Lines represent the coordinates of two polygons, given in counter-clockwise
// (or clockwise) order, which we will call "4" and "8". The last line
// contains a list of points, p[1], p[2], ...
// Our goal is to determine:
// (1) whether 8 - A is a single closed shape (as opposed to multiple shapes)
// (2) the area of 8 - A
// (3) whether each p[i] is in the interior of 8 - A
// (3) whether each p[i] is in the interior of 8 - A
// (4) whether each p[i] have a considered by the interior of B - A
// (5) the area of 8 - A
// (6) He is a singular.
```

```
// make an array of doubles from a string

// inferred directly from the code. For each sentence in the input, we must
// determine whether the sentence matches the regular expression or not. The
// code consists of (1) building the regular expression (which is fairly
// complex) and (2) using the regex to match sentences.
// Code which demonstrates the use of Java's regular expression libraries. 
 // This is a solution for

#### KMP.cpp 33/35

```
Searches for the string w in the string s (of length k). Returns the \theta-bosed index of the first match (k if no match is found). Algorithm runs in O(k) time.
                                                                                                                                                                                                                                                                                                                                                                                                                                                 iffw[i-1] == w[j]) { t[i] = j+1; i++; j++; } else if(j > 0) j = t[j]; else { t[i] = 0; i++; }

$\frac{1(T(n) - 3(T(n/2))}{3(T(n/2))}$	(o/m/)[-u - solo	$3^{2} \cdot s_{2} = \frac{1}{2} (T(2) - \frac{1}{2})$ Let $m = \log_{2} n$ .	we get $I(n) = 3^m$ $T(n) = n^k$ where $l$ Summing the right	m_1
Master method: $T(n) = aT(n/b) + f(n),  a \ge 1, b > 1$ If $\exists c > 0$ and that $f(n) = O(n\log_k a^{-c})$	then $T(n) = \Theta(n^{\log_b a}).$	If $f(n) = \Theta(n^{\log_b a})$ then $T(n) = \Theta(n^{\log_b a} \log_2 n).$	If $\exists \epsilon > 0$ such that $f(n) = \Omega(n^{\log b} a^{+\epsilon})$ , and $\exists c < 1$ such that $af(n/b) \le cf(n)$	for large $n$ , then

Substitution (example): Consider the  $T_{i+1} = 2^{2^i} \cdot T_i^2, \quad T_1 = 2.$  $T(n) = \Theta(f(n)).$ following recurrence

Let  $u_i=t_i/2^i$ . Dividing both sides of the previous equation by  $2^{i+1}$  we get  $\frac{t_{i+1}}{2^{i+1}}=\frac{2^i}{2^{i+1}}+\frac{t_i}{2^i}.$ Note that  $T_i$  is always a power of two. Let  $t_i = \log_2 T_i$ . Then we have  $t_{i+1} = 2^i + 2t_i$ ,  $t_1 = 1$ .

which is simply  $u_i = i/2$ . So we find that  $T_i$  has the closed form  $T_i = 2^{i2^{i-1}}$ . Summing factors (example): Consider  $u_{i+1} = \frac{1}{2} + u_i, \quad u_1 = \frac{1}{2},$ Substituting we find

Rewrite so that all terms involving  ${\cal T}$  are on the left side  $T(n) = 3\overline{T}(n/2) + n, \quad T(1) = 1.$ T(n) - 3T(n/2) = n.

the following recurrence

Now expand the recurrence, and choose a factor which makes the left side "tele-

Summing the left side  $^{m}T(1)=T(n)-3^{m}=$   $^{2}k=\log_{2}3\approx1.58496.$  It side we get -3T(1) = 2

 $= 2n(c^{(k-1)\log_c n} - 1)$  $\sum_{i=0}^{m-1} \frac{n}{2^i} 3^i = n \sum_{i=0}^{m-1} \left(\frac{3}{2}\right)^i.$  $= 2n(c^{\log_2 n} - 1)$ Let  $c = \frac{3}{2}$ . Then we have  $n \sum_{i=0}^{m-1} c^i = n \left( \frac{c^m - 1}{c - 1} \right)$ 

and so  $T(n) = 3n^k - 2n$ . Full history recurrences can often be changed to limited  $T_i = 1 + \sum_{j=0}^{i-1} T_j, \quad T_0 = 1.$ history ones (example): Consider  $= 2n^k - 2n,$ 

 $T_{i+1} - T_i = 1 + \sum_{j=0}^i T_j - 1 - \sum_{j=0}^{i-1} T_j$  $T_{i+1} = 1 + \sum_{j=0}^{i} T_j.$ Subtracting we find Note that

And so  $T_{i+1} = 2T_i = 2^{i+1}$ .  $=T_i$ .

2. Sum both sides over all i for which the equation is valid.

Choose a generating function G(x). Usually G(x) = ∑<sub>i=0</sub><sup>x</sup> x<sup>i</sup>g.
 Rewrite the equation in terms of the generating function G(x).
 Solve for G(x).
 The coefficient of x<sup>i</sup> in G(x) is g<sub>i</sub>.
 Example:

 $g_{i+1} = 2g_i + 1, \quad g_0 = 0.$ 

Multiply and sum:  $\sum_{i \geq 0} g_{i+1} x^i = \sum_{i \geq 0} 2g_i x^i + \sum_{i \geq 0} x^i.$ 

We choose  $G(x) = \sum_{i \geq 0} x^i g_i$ . Rewrite in terms of G(x):  $\frac{G(x) - g_0}{x} = 2G(x) + \sum_{i \geq 0} x^i.$ 

Simplify:  $\frac{G(x)}{G(x)} = 2G(x) + \frac{1}{1-x}.$ 

 $G(x) = \frac{x}{(1-x)(1-2x)}$ Solve for G(x):

Expand this using partial fractions:  $G(x) = x \left( \frac{2}{1-2x} - \frac{1}{1-x} \right)$ 

 $= x \left( 2 \sum_{i \ge 0} 2^i x^i - \sum_{i \ge 0} x^i \right)$ 

 $= \sum_{i \ge 0} (2^{i+1} - 1) x^{i+1}.$ 

So  $g_i = 2^i - 1$ .
